Types of Myocardial Infarction

- **Type 1: Spontaneous myocardial infarction**
  - Due to atherosclerotic plaque rupture, ulceration, fissuring, erosion or dissection with resulting intraluminal thrombus leading to decreased myocardial blood flow or distal platelet emboli with ensuing myocyte necrosis.

- **Type 2: Myocardial infarction secondary to an oxygen supply-demand mismatch**
  - A condition other than CAD contributes to an imbalance between myocardial oxygen supply and/or demand, e.g. coronary artery spasm, anemia, respiratory failure, hypotension, sepsis, etc.

- **Type 3: Myocardial infarction resulting in death when biomarkers values are unavailable**
  - Ex: a patient passes in the ED before lab work can be drawn

- **Type 4a: Myocardial infarction related to percutaneous coronary intervention (PCI)**
  - Acute post-PCI troponin elevation > 5 times the 99th percentile of upper reference limit (URL) plus one of the following:
    - Symptoms suggestive of myocardial ischemia
    - New ischemic ECG changes or new LBBB
    - Angiographic loss of patency of a major coronary artery
    - Imaging demonstration of new loss of viable myocardium or new wall motion abnormality

- **Type 4b: Myocardial infarction related to stent thrombosis**

- **Type 5: Myocardial infarction related to coronary artery bypass grafting (CABG)**
  - Acute post-CABG troponin elevation > 10 times the 99th percentile URL plus one of the following:
    - New Q waves or new LBBB
    - Angiographic documented new graft or new native coronary artery occlusion
    - Imaging demonstration of new loss of viable myocardium or new wall motion abnormality

*Third Universal Definition of Myocardial Infarction, Published August 2012*
